In the last year, the invasive Indo-Pacific Amphibian, *Batrachochytrium dendrobatidis* (Bd), has caused the extinctions of at least five species of amphibians around the globe, with some parts of the world experiencing a wave of extinctions nearly equal to that of the rapid-onset mass extinctions witnessed during the extinction event at the end of the Paleogene epoch. A paper published this week in *Science* summarizes the findings of some of the most comprehensive genetic research conducted to date with regard to the prevalence of Bd in affected areas, and paints a troubling picture of the state of amphibian populations in the face of Bd's devastations. Bd is an exceedingly simple organism, holding a minimum of seven genes with notable levels of horizontal transmission. It exploits the symbiotic relationship that most amphibians hold with their skin communities of micro- and macro-organisms to cause mass-scale amphibian deaths, and spread to new regions

through the movement of individuals. Because it's a fungal pathogen, the infected individuals are unable to fight off the infection, and succumb to an eventual death by the tens of thousands, or even millions. The last 12 months has seen a flurry of research confirming the existence of an amphibian crisis in the form of mass extinction in the Western Hemisphere. Countries such as Panama, Colombia, Ecuador, Peru, and Brazil have seen species disappear, sometimes within months. The fungus has also hit the species that survive its effects in the form of extreme malnutrition, and at least two other extinctions are confirmed and under review by international authorities. In an effort to develop proper solutions for these threats, researchers have been turning their attention towards finding a way to use genetics to keep a close eye on amphibian populations. The foremost research project to use genetics to monitor amphibian health has been that of Germany's Leibniz Institute of Freshwater Ecology and Inland Fisheries (IGB), with a focus on amphibians in Germany. To do so, the IGB, along with several other international research organizations, has turned to a group of common frogs (*Rana temporaria*), which are ubiquitous in Europe, and found all over the world. A team of researchers from
